

SDS Scenario #2

Mark Elkington/Ron Williamson

System Design Review - 28 June 1994

SDS Scenario #2 - User Interaction Science Overview

User Model Scenario #7 (*"Development of a method to integrate data sets of varying resolution"*)

Develop technique to integrate data from sensors of varying spatial, temporal, spectral resolutions

1 2 3 4 5

Model**

13
Standing
Request

**NDVI 10-day
Composite**

Standing
DAR

ASTER

Process

**ASTER
derived NDVI**

Scenario #2 - Step 0

User sets up connection to EDC Data Search Service

- **User looks for Landsat-7 services to help find data for the region of interest**

- **Move service reference to Desktop**

Scenario #2 - Step 1

User uses search service interface to submit a query for Landsat-7 data. is submitted and the results returned for review and selection by the user

- **establishes existing session**
- **Open Desktop Search Application - creates session with context**
- **Formulates Data Search Request - uses data dictionary to understand terms**
- **Specifies Search Parameters (sensor=Landsat7, space=region defined by polygon, time=range, processing level=L0R, results format = sorted, selectable, list)**

- **List of matching data received**

Scenario #2 - Step 2

User views query results, selects appropriate granules based on location and quality information

- **Views Result set through Desktop Viewers**
- **Selects a Landsat 7 result entry**
- **Requests a single band subset**
- **Specifies protocol for resulting data (ftp)**

- **Single band image returned to desktop**

Scenario #2 - Step 3, 4 & 5

The user inspects single band image to establish suitability; requests full data granule for each of the selected images

- Inspects image using image browse and visualization tools
- Searches for cloud free areas, flat & varied terrain, static features over 3 week period

user may use system to collaborate with colleagues

- Repeats Steps 2 and 3 until satisfied with results
- Requests delivery of full data granules using overnight file transfer

- data received

Scenario #2 - Step 6, 7

User searches for DEMs available for the region of interest.

- User asks for information on the DEM Providers

system searches Advertisements for
DEM Providers and provides links to
associated Guide information

- Accesses guide information on each provider to verify DEM content, extent, format, quality - establishes that best provider is a research group associated with the SCF at 'Univ_of_X'
 - Requests DEM
-
- Receives DEM

Scenario #2 - Step 8, 9, 10

The user requests a list of MODIS Level 1B data which are geographically and temporally coincident with the Landsat granules previously selected.

- User uses Advertising Service to access MODIS Level 1B service provider (GDAAC)

uses advertising service as
described in Step 0

- Specifies query for MODIS data using the saved results from the Landsat-7 search

- MODIS data received at desktop

Scenario #2 - Step 11

Scenario #2 - Step 12

- User prepares method using 'ingest preparation toolkit' on desktop. Transfers method to LPDAAC 'method' ingest service

system ingests method and associated files

- User is informed of availability of I&T resource and establishes an algorithm/method I&T session (has already read Guide material on method I&T).

system supports user in performing method I&T. User passes method to DAAC I&T staff for association with Data Server

- User is notified that method is available at LPDAAC

Scenario #2 - Step 13

- User prepares a processing request, that will be activated every 10 days. The processing request identifies:
 - process (surface_model_method)
 - frequency of activation (10 days- for period ending 3 days before)
 - action on completion (notify availability)
 - error action (notify, temporary save of intermediate results), and
 - other method specific processing parameters

**system takes processing request and
activates processing as requested**

- User receives notification of production completion and uses the embedded UR in request to retrieve it

Scenario #2 - Step 14, 15

The user establishes a Data Acquisition Request (DAR) for cloud-free ASTER scenes to be acquired at within the

- through advertising service, user identifies the ASTER production service
- using the DAR service interface installed on the desktop user specifies required data and the processing parameters

system processes DAR and provides user with notifications each time a suitable image is acquired & further notification when it is processed

- user receives notification each time a cloud-free scene for the defined region is processed
- user requests dissemination of the data

- user receives the data for verification of the NDVI surface model and stores it in their local SCF Data Server.
